There are many factors to bear in mind when addressing deep learning training and inference. Here's a quick guide to help you identify the optimal tool to meet your specific needs.

# **BEFORE YOU GET STARTED, CONSIDER THESE QUESTIONS:**

What are your

cost constraints?

What type of hardware

or server rack?

Can you train during off-peak hours?

Can you deal with the software complexities of multiple architectures?

## Though only 10 to 15% of a typical workflow, training a model is a key step in harnessing the power of artificial intelligence. In this phase, the algorithm seeks to learn features and patterns from the data

TRAINING

you feed it, later applying that knowledge to unseen data. Think of showing millions of examples of bone images to an algorithm that will be trained to identify bone density for radiologists. Training can take several hours to several days. **CPUs GPUs** 

architecture do you already

have in your workstations

deep learning on language, text, and time-series data—CPUs shine. This is especially true for memory-intensive data, including massive amounts of unstructured data as well as sparse data. Infrequent training (fewer than 10 times per year) may also be a factor in staying on CPUs. **Pros** 1. Al applications can be run side by side

definition-, 3D-, and non-image-based

## with other applications, maximizing

- hardware utilization 2. Larger, memory-intensive models can be trained with greater ease 3. Data can be accessed from the same
- the time it would take to port data from one architecture to another 4. Utilization can be maximized, which

infrastructure on which you train, saving

can contribute to improved total cost of

- ownership 5. Public cloud instances of CPUs are typically far less expensive than GPUs, especially when training for extended periods on large models
- alternative to GPUs Cons 1. If you are training models frequently,

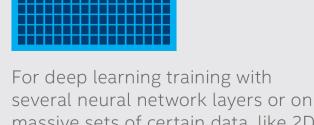

6. If your training workload is not time sensitive, CPUs may be a viable

#### the lower speed can potentially cost you valuable time

more cycles with a CPU than when using a GPU

2. The same training will typically require

**INFERENCE** 

massive sets of certain data, like 2D images, GPUs or other accelerators can be your best bet. GPUs also tend to be the better choice for fast deep learning as the simple matrix math calculations greatly benefit when computations can be done in parallel. **Pros** 1. Fast training on certain types of data

#### 1. Hardware may not be utilized to full capacity

Cons

- 2. Memory limitations require you to break down images or your model, resulting in
- more work and/or subpar results 3. Data must be ported from one architecture to another when transferred

from GPUs to CPUs in the data center

- 4. Can add cost, complexity, and operational expenses

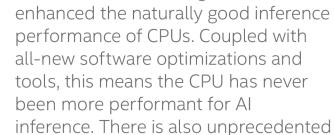

### After your model is trained, you'll put it to work with inference, or the inferring of something about data it has never seen before. Inference cycles already surpass those of training by anywhere from 10x to 1000x, depending on the application. Today, inference primarily runs on CPUs, and a typical

**CPUs** 

for 100% of its current inference applications. As deep learning has been adopted more broadly, there has been a clear shift in the ratio between cycles of inference and training. Our conservative internal estimate predicts a move from 1:1 in the early days of deep learning to potentially more than 10:1 by 2020. With inference taking a large majority of the workflow, it is critical to use hardware architectures well suited to those needs, meaning low latency and often low power.

deployment will use a mix of neural networks and other types of compute power. Facebook uses CPUs

Recent hardware changes have GPUs excel at performing matrix

robust and sustained inference applications. As inference is not as resource heavy as training, CPUs are economical as well. **Pros** 1. Real-world applications have increasingly stricter latency, a CPU strength 2. The newest CPUs can support much more of the system memory required for complex models 3. CPUs can extend further to the edge, including devices, unlike GPUs, allowing a similar architecture from training through

diversity in acceleration hardware for

### deployment 4. CPUs are well suited to new options like using pretrained models or transfer learning

Cons Given today's inference demands and the capabilities of current technology there

are no significant downsides to using a

smart speakers, and vehicles, etc.

workstations, robotics, some phones and

5. CPUs already power laptops,

CPU for inference.

Though we focus here on CPUs and GPUs, there are certain inference environments that are not especially

well suited to CPUs and GPUs,

for data center or cloud-based

such as very small devices. Even

inference, sometimes the workloads

are simply too sustained or of too

high a volume for CPUs or GPUs to

cases, other tools may be preferred,

integrated circuits (ASICs), and field-

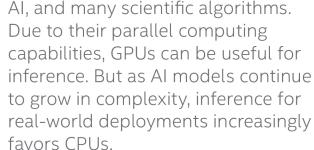

programmable gate arrays (FPGAs).

make economical sense. In these

including vision processing units (VPUs), application-specific

# operations that relied on by graphics,

**GPUs** 

**Pros** 1. When inference speed is a bottleneck, GPUs can provide financial and time gains 2. By design, GPUs can work well for tasks like image recognition 3. GPUs may be a cheaper option today Cons 1. GPUs have inherent memory constraints 2. GPUs can be power hungry, which conflicts with the needs of edge devices

3. GPUs are less common in infrastructure

upgraded to support AI applications

that may already need to be utilized and

**VPUs** – VPUs are ultralow-power computer vision engines and

offer capabilities for inference for low-power devices such as

ASICs – Technically, a GPU is an ASIC used for processing

performing fixed operations extremely fast since the entire

chip's logic area can be focused on a narrow set of functions,

graphics algorithms. A custom ASIC is dedicated to

making them suitable for a high degree of parallelism.

FPGAs – With particular value for high-throughput, low-

latency inference applications, FPGAs offer a unique blend

of flexibility, performance, and extensibility unmatched by

smart cameras and network video recorders.

custom ASICs or GPUs.

2nd Gen Intel® Xeon® Scalable processor (intel) platform performance **XEON** Al includes a wide variety of machine learning and analytics techniques, but its connection with deep learning has most captured the interest and imagination of today's innovators. Intel® Xeon® Scalable processors are optimized specifically to run highperformance deep learning inference. Most deep learning, including computer vision and inference, already runs on Intel® Xeon® processors as they are the foundation of many of the world's data centers. The hardware performance of AI applications can further benefit from software optimizations. Our new 2nd Generation Intel Xeon Scalable processors have AI built in, offering significant leaps in inference performance, memory, and bandwidth that accelerate complex AI applications. The processors have been enhanced with substantial improvements in software optimizations and hardware instructions, giving you the flexibility you need for both AI and the vast range of data-centric applications. Intel® Deep Learning Boost technology – This cross-platform tool features a model optimizer and inference engine to streamline and simplify model

inference performance.2

deployment. Access a new set of embedded accelerators (vector neural network instructions, or VNNIs) to speed up the dense computations of convolutional neural networks (CNNs) and deep neural networks (DNNs). The low-precision integer operations deliver up to 30x improvement in

**Intel® Optane™ DC persistent memory** – Achieve up to triple the maximum

achieved using an Intel® Xeon® Platinum 8180 processor running Intel-optimized Caffe\* GoogLeNet\* v1 with Intel® Math Kernel Library for Deep Neural Networks (Intel® MKL-DNN), vs. an Intel® Xeon® processor E5-2699 v3 with BVLC-Caffe<sup>3</sup>

storage per node and enable more memory closer to the CPU so data can be sustained even throughout power cycles or system maintenance. This is AI on Intel. To boost performance, we've also optimized the software tools and frameworks widely used today for Intel Xeon Scalable processor-based platforms:
